Explanation of our visualisations and the implications of sentiment in the Game of Thrones script, followed by reflections on the limitations of our visualisations.

Our visualisation represents a sentiment analysis of what different emotions and sentiments the manuscript from Game Of Thrones contains. The y-axes is "n" meaning the numeric value of words, and the x-axes is the eight emotions and two sentiments. The analysis is done with the NRC word-emotion lexicon, that is a list of English words and their associations with these eight basic emotions; anger, anticipation, disgust, fear, joy, sadness, surprise and trust. The words are then also associated with two sentiments; positive or negative. The words in the NRC lexicon have manually been categorised by many people online - called crowdsourcing.

The results the visualisation shows is that the “trust” is the emotion with most words associated to it from the script. “Trust” we would guess is categorised under “positive” sentiment, and it helped the results of our analysis, that is that the script's sentiment overall is a little bit more positive than negative. Though the difference is not remarkable. Which may come as a surprise when we are dealing with Game of Thrones. “Fear” has the third most words associated with it from the script. There are fewest words associated with “surprise” in the script. The limits of the visualisation is that we are not informed what words belong under which emotion and sentiment, and that it can be hard to define what emotion should be associated with the words. Another limit is that the words in the script are analysed text-based, which makes it hard to know the context of the word, and thereby to understand with what emotion the word was intended, because it may have been said in irony or something else. Many words can also have two meanings, for example the adjective “terrific”, which can both be positively or negatively understood. This ambiguity is a limit of this type of sentiment analysis and visualisation.
